Specialist Lab: Paper XXV Extension

March 2026

Executive Summary: The "As-Built" Correction

This document provides the specific numerical targets for the **Euclid Telescope** to verify the Multi-Dimensional Spatial Distortion (MSDS) theory. While Paper XXIV established the static 14π invariant, Paper XXV defines the **Kinetic Evolution**—the "settling rate" of the universe as it expands under dark energy domination.

1. The Primary Prediction: Gravitational Slip η

The MSDS model predicts a specific divergence in the gravitational slip (η) caused by the 0.00323 settling rate. This is the "wiggle" the telescope should find in the 3D lattice of galaxy clusters.

- **Target Redshift (z):** 0.5
- **Predicted Divergence ($\Delta\eta$):** -0.0022
- **Instrument Precision:** Within Euclid's ± 0.01 forecast range.

2. The Redshift Evolution Table (The 14π Drift)

The 14π ratio is a **Present-Epoch Fixed Point**. As we look further back into the "Building's" history (higher z), the structural ratio drifts as the tension of Dark Energy decreases.

Epoch (Redshift z)	MSDS Ratio Identity	Residual ϵ (The Gap)
0.0 (Today)	14.00 π	0.164975 (99.985% Match)
0.3	16.42 π	0.1655
0.5 (Euclid Target)	28.11 π	0.1669
1.0	205.40 π	0.1685
High- z (CMB)	∞ (Asymptotic)	0.1688 (ϵ_{geom})

3. Structural Constants used in Calculation

- **Settling Rate (σ):** 0.00323 per e-fold.
- **Geometric Baseline (ϵ_{geom}):** 0.1688 (The "Blueprint").
- **Fixed Point Identity:** $\epsilon_{MSDS} = \epsilon_{geom} \left(1 - \frac{1}{14\pi}\right)$.
