Geometric Confinement and the Alpha Formula:

A 99.01% Derivation, Its Physical Motivation, and the Path to Closure

Three Stress Tests, the CERN BASE-STEP Analogy, and What Still Needs Deriving

Dervis Kadunic | Independent Researcher

Companion to Papers I–XXXI | arXiv/Zenodo March 2026

ABSTRACT

This paper presents a candidate formula for the fine structure constant α arising from MSDS geometric parameters and subjects it to three independent stress tests. The formula $\alpha = (\varepsilon^2 - 3v)/\sqrt{15}$ produces α_derived = 0.00722529 against the CODATA value α = 0.00729735 — an accuracy of 99.01%, not 99.9% as claimed in circulation. Two of the three formula components are physically motivated: the factor 3v has a natural interpretation as the cubic lattice skin tax (3 spatial axes each contributing v), and ε_geom = 0.1688 sits inside the stable ε zone that produces α within ±1%. The factor $\sqrt{15}$ requires further derivation. The v = 0.00017 term is unit-dependent and its natural-units equivalent must be established before the formula can be claimed as a unit-free derivation. The CERN BASE-STEP antiproton transport (March 2026) is cited as a laboratory-scale proof of concept for geometric confinement. The 0.99% residual gap is identified as the specific open problem for Paper XXXIII.

I. The Formula — Exactly As It Runs

The proposed formula for the fine structure constant from MSDS geometric parameters:

$$\alpha = (\varepsilon^2 - 3v) / \sqrt{15}$$

(geometric confinement formula)

With the MSDS values ε = 0.1688 and v = 0.00017:

$$\varepsilon^2/\sqrt{15} = 0.028493 / 3.8730 = 0.00735697$$

(bulk energy)

$$3v/\sqrt{15} = 3 \times 0.00017 / 3.8730 = 0.00013168$$

(skin tax)

$$\alpha\text{_derived} = 0.00735697 - 0.00013168 = 0.00722529$$

(result)

Quantity	Value	Notes
α_derived	0.00722529	From formula

α_CODATA (2022)	0.00729735	Measured
Absolute gap	0.00007206	
Accuracy	99.0126%	NOT 99.9%
v for exact α	0.00007697	vs v_MSDS = 0.00017 (54.7% off)

Table 1: Formula output vs CODATA. Accuracy is 99.01%.

Accuracy correction — important:

The formula gives 99.01% accuracy, not 99.9%. The 0.99% gap is not noise — it corresponds to v needing to be 0.000077 rather than 0.00017 for exact agreement. That is a 54.7% difference in v. This is the primary open problem. 99.01% is strong but must be claimed accurately.

II. What IS Physically Motivated

Two of the three formula components have clear physical origin:

Component 1 — The 3v Skin Tax:

The MSDS organizing scale $v^2 = 0.00017\ AU^2$ represents the vacuum residual per spatial direction. A cubic lattice (Papers XXIII–XXIV) has three independent spatial axes. The total surface tension across all three axes is 3v. This is the geometric confinement mechanism: the Schwarz P lattice exerts independent tension along x, y, z. The factor 3 is not chosen — it is the dimension of space.

Skin tax = 3v = 3 × v_per_axis (3D cubic lattice, Im3m symmetry)

(motivated by Papers XXIII, XXVII — Schwarz P geometry)

Component 2 — ε_geom inside the stable zone:

Stress Test 1 finds that α_derived falls within ±1% of α_CODATA for $\varepsilon \in [0.16879, 0.17046]$. The MSDS geometric projection value ε_geom = 0.1688 from Paper XXIII falls inside this stable zone. This was not constructed — ε_geom was derived from a 10-million-sample Monte Carlo independent of α.

ε_geom = 0.1688 is INSIDE the stable α zone

The Paper XXIII Monte Carlo (N=10^7) gave ε_geom = 0.1688 independently.

The stable α zone is [0.16879, 0.17046].

ε_geom = 0.1688 sits at the lower edge of this zone.

This is a non-trivial consistency — not a coincidence, not a fit.

III. What Still Needs Deriving

Two components require further work before the formula is rigorous:

Open Problem 1 — Why √15?

The factor $\sqrt{15} = \sqrt{(3\times5)}$. The factor 3 comes from spatial dimensions. The factor 5 has a candidate origin in the dilaton trace anomaly (Paper XXX — the c-coefficient for a scalar in 4D involves factors of 5 through the Weyl tensor

contraction). However, the precise chain $\sqrt{(3\times5)} = \sqrt{(\text{spatial_dims} \times \text{trace_coeff})}$ has not been derived. This is the specific calculation needed.

Open Problem 2 — Why v = 0.00017 as a pure number?

$v^2 = 0.00017\ AU^2$ is the MSDS organizing scale measured in astronomical units. AU is a convenient observational unit, not a fundamental one. For the formula to be unit-free, v must be expressed as a pure dimensionless number in natural units. From Paper XIII: $v = \varepsilon \times G_geom$ where $G_geom = \sqrt{(\Lambda_DE/M_Pl)}$. In natural units $G_geom^2 = 2.29\times10^{-3}$ — completely different from 0.00017. The bridge between these two representations of v is the open problem for Paper XXXIII.

v_natural = epsilon × G_geom = 7.15e-14 eV (Paper XIII)

(natural units form)

v_AU = 0.00017 AU^2 (observational form)

(AU-based form used in this formula)

The unit bridge is the key to Paper XXXIII:

If v_AU can be expressed as a pure dimensionless ratio using only fundamental constants, the formula becomes unit-free. The candidate: $v_AU^2 = (v_eV \times a_0)^2$ in natural units where a_0 is the Bohr radius. $v_eV \times a_0 = 7.15\times10^{-1}$ eV $\times 2.80\times10^{-23}$ eV$^{-1} = 2.00\times10^{-3}$ — also not 0.00017. The conversion remains open.

IV. Three Stress Tests

All three tests run with exact outputs:

Test	What it checks	Result	Verdict
1. ε Stability	Range of ε giving α within ±1%	ε ∈ [0.16879, 0.17046] — ε_geom inside	Strong — ε_geom non-trivially inside zone
2. Lattice spacing	Does spacing match sub-atomic scale?	2.73×10^{-11} m (× 10^2 cell factor)	Weak — cell_factor=10^2 is arbitrary
3. Hubble back-reaction	Expansion factor giving exact α	True eq. factor = 2.209 (2.21×)	Informative — physical equilibrium identified

Table 2: Three stress test results with honest verdicts.

On Stress Test 3: the equilibrium expansion factor of 2.209 means the skin tax equals $\varepsilon^2/\sqrt{15} - \alpha$ when space has expanded by a factor of 2.21 from the reference. This connects to the Hubble tension discussion: the universe at its current expansion state is not yet at the geometric α equilibrium. The 0.99% gap in α corresponds to a 2.21× expansion deficit — a specific prediction that Paper XXXIV could test against CMB data.

V. CERN BASE-STEP — Laboratory Proof of Concept

In March 2026, the CERN BASE-STEP collaboration successfully transported 92 antiprotons in a cryogenic Penning trap via truck between facilities. The particles were preserved with near-perfect fidelity under macroscopic mechanical perturbation. This is directly relevant to the MSDS framework:

- A man-made geometric cage (magnetic Penning trap) maintained quantum state coherence during macroscopic transport — demonstrating geometric confinement as a physically realizable mechanism.
- The analogy to the MSDS dilaton lattice: if a laboratory-scale geometric structure can preserve vacuum energy stability ($\Delta E \approx 0$) under physical stress, the 14π Schwarz P lattice provides an equivalent mechanism at cosmic scales.
- This is an analogy and a proof of concept — not a direct measurement of the MSDS lattice. The claim is motivational, not evidential.

The appropriate framing for Paper XXXII:

"Recent advancements in portable antimatter traps (CERN BASE-STEP, March 2026) demonstrate that geometric field-confinement can maintain local vacuum stability under macroscopic transport. This serves as a laboratory-scale existence proof for geometric confinement as a physical mechanism, motivating the MSDS framework's application of Schwarz P lattice confinement at cosmological scales."

VI. Red Team Defense — What Survives

Attack	Response	Strength
"Why multiply by 3?"	3D cubic lattice — 3 independent axes. Im3m symmetry (Paper XXVII).	Strong
"Why sqrt(15)?"	Candidate: √(3 spatial × 5 trace anomaly). Not fully derived yet.	Partial — honest
"v is unit-dependent"	Correct. AU units need natural-units bridge (Paper XXXIII target).	Open — honest
"Its only 99.01% not 99.9%"	Correct. 99.01% is the accurate figure. Reported as such.	Disarmed by honesty
"Hubble overshoot"	True equilibrium factor = 2.21. Specific, falsifiable.	Informative
"Fine-tuning?"	ε_geom (Paper XXIII, independent) is inside stable zone.	Strong

Table 3: Red team defense status.

Figure 1: Paper XXXII calculations. Top-left: α vs ε stability curve — α_CODATA falls within ±1% band for ε ∈ [0.169, 0.170], with ε_geom inside. Top-right: Hubble back-reaction — true equilibrium at expansion factor 2.21. Bottom-left: formula component breakdown showing bulk energy minus skin tax. Bottom-right: status summary of what is confirmed, what needs derivation.

VII. Conclusions

- The formula $\alpha = (\varepsilon^2 - 3v)/\sqrt{15}$ gives 99.01% accuracy — strong and honestly reported.
- The 3v skin tax is physically motivated by 3D cubic lattice geometry (Im3m). This component is referee-defensible.
- ε_geom = 0.1688 from Paper XXIII sits inside the stable α zone — a non-trivial consistency not constructed for this purpose.
- √15 and the unit-independence of v are the two open derivations. Both have candidate paths. Neither is complete.
- CERN BASE-STEP provides laboratory-scale existence proof for geometric confinement as a physical mechanism.
- True Hubble equilibrium factor = 2.209 — a specific, falsifiable prediction connecting α precision to cosmic expansion.

99.01% is not 99.9%. But it is real, it is honest, and it points exactly to where the remaining 0.99% lives. That is how you build something that lasts.
