Paper LV

The MSDS Cosmological Auditor:

A Four-Channel Forensic Instrument for the Structured Vacuum

From Side-Channel Attack Logic to Cosmological Signal Detection

η(z) · S8=0.7890 · A_lens=0.9781 · β=0.216° · All four channels: PASS

ABSTRACT

We present the MSDS Cosmological Auditor — a four-channel forensic instrument that tests the MSDS structured vacuum framework against independent observational datasets using all parameters fixed from Papers I-LIII. The instrument was developed by applying the logic of Correlation Power Analysis (CPA) — the methodology used to extract hidden keys from encrypted hardware — to cosmological data: subtract the dominant signal, isolate the residuals, correlate with a fixed model. The four channels are: (1) gravitational slip η(z), targeting Euclid DR1 (2026); (2) S8 tension, targeting KiDS/DES/Rubin; (3) CMB lensing amplitude A_lens, from Planck PR4; (4) cosmic birefringence β, targeting LiteBIRD (2030). Results: η(z=0.5) = 0.8967 (5.2σ from GR); S8 = 0.7890 (0.3σ from KiDS-1000, down from 2.9σ in GR); A_lens = 0.9781 (1.2σ from Planck PR4); β_floor = 0.2159° (1.3σ from Eskilt and Komatsu 2022, 3.6σ signal). All four Titanium Kill Conditions are currently unfired. The framework is not confirmed — it is untested at the required precision. Euclid 2026 and LiteBIRD 2030 will decide.

1. The Auditor Architecture: From Encryption to Cosmology

The MSDS Auditor was inspired by an architectural insight from Dervis Kadunic: the same logic used to break AES-128 encryption via side-channel attacks applies to extracting weak signals from noisy cosmological data.

CPA (AES Attack)	Cosmological Auditor
Power traces (noisy)	Cosmological observations (noisy)
Subtract mean signal	Subtract GR/Newtonian baseline
Correlate with Hamming weight model	Correlate with MSDS kernel model
Peak identifies true key byte	Peak identifies true $v^2 = 0.00017$
5000 power traces	5000+ years of astronomical data
16/16 key bytes recovered	Four channels pass simultaneously

Table 1: The CPA analogy. The methodology transfers — the correct estimator for the planetary case is OLS (matched filter), not Pearson correlation.

One critical lesson learned during development: Pearson correlation is scale-invariant. For the planetary application (recovering v^2 from Jupiter-Saturn orbital residuals), the correct estimator is OLS: v^2_recovered = Σ(model × residuals) / Σ(model²). This is the matched filter — it extracts amplitude directly. At telescope-era precision (1 arcsecond, 500 observations), the OLS estimator recovers $v^2 = 0.00017$ with 0.6% error. At Gaia precision, recovery is exact. The real JPL ephemeris test awaits pre-cleaned DE440 residuals.

2. Channel 1 — Gravitational Slip η(z)

eta(z) = (1 - T(z) Delta_0 (1+z)^(3/4)) / (1 + T(z) Delta_0 (1+z)^(3/4))

T(z) = [1+((1+z)/(1+z_t))^(9/2)]^(-1), z_t=1.98, Delta_0=0.042, p=3/2

z	η(z) MSDS	T(z)	Euclid σ	σ from GR	Zone
0.3	0.90486	0.97681	±0.030	3.17σ	MSDS active
0.5	0.89670	0.95675	±0.020	5.17σ	MSDS active
0.7	0.89048	0.92644	±0.020	5.48σ	MSDS active
1.0	0.88567	0.85839	±0.020	5.72σ	MSDS active
1.3	0.88696	0.76369	±0.025	4.52σ	MSDS active
1.6	0.89404	0.65052	±0.035	3.03σ	Redshift Desert
2.0	0.90962	0.49434	±0.040	2.26σ	Redshift Desert
2.5	0.93186	0.32820	±0.060	1.14σ	Redshift Desert

Table 2: Euclid bin predictions. Redshift Desert bins show η rising toward GR — the Paper LIII fingerprint. Kill: flat η(z) across desert.

3. Channel 2 — S8 Tension

S8_MSDS = sigma8 × Sigma_eff × (Omega_m/0.3)^0.5 = 0.7890

Sigma_eff = 0.94946 from full lensing kernel integral | 2.9sigma → 0.3sigma

- S8 (GR prediction): 0.8310 → 2.9σ tension with KiDS-1000
- S8 (MSDS): 0.7890 → 0.3σ from KiDS-1000 = 0.7849 ± 0.016
- Kill condition: S8 > 0.810 from future weak lensing surveys

4. Channel 3 — CMB Lensing A_lens

A_lens = integral[W_CMB(z) × Sigma²(z) dz] = 0.97808

Planck PR4: 1.005 ± 0.023 | Tension: 1.17sigma

- Paper L formula (unmodulated): A_lens = 0.727 — over-suppresses CMB lensing
- Paper LIII (saturation kernel): A_lens = 0.9781 — consistent with Planck PR4
- Kill condition: A_lens < 0.95 (Rubin/Simons Observatory ~2027)

5. Channel 4 — Cosmic Birefringence

beta_floor = 10^7 × (v²)^2.5 × (180/pi)° = 0.2159°

Three-step bipolar suppression (Paper LIV): n=2.5 → geometric floor

- MSDS geometric floor (n=2.5): β = 0.2159°
- Full observed signal (n=2.447): β = 0.342° — requires derivation of g_CS from MSDS action
- Eskilt and Komatsu 2022: β_obs = 0.342° ± 0.094° (3.6σ signal in Planck PR4)
- Kill condition: β < 0.15° (LiteBIRD 2030)

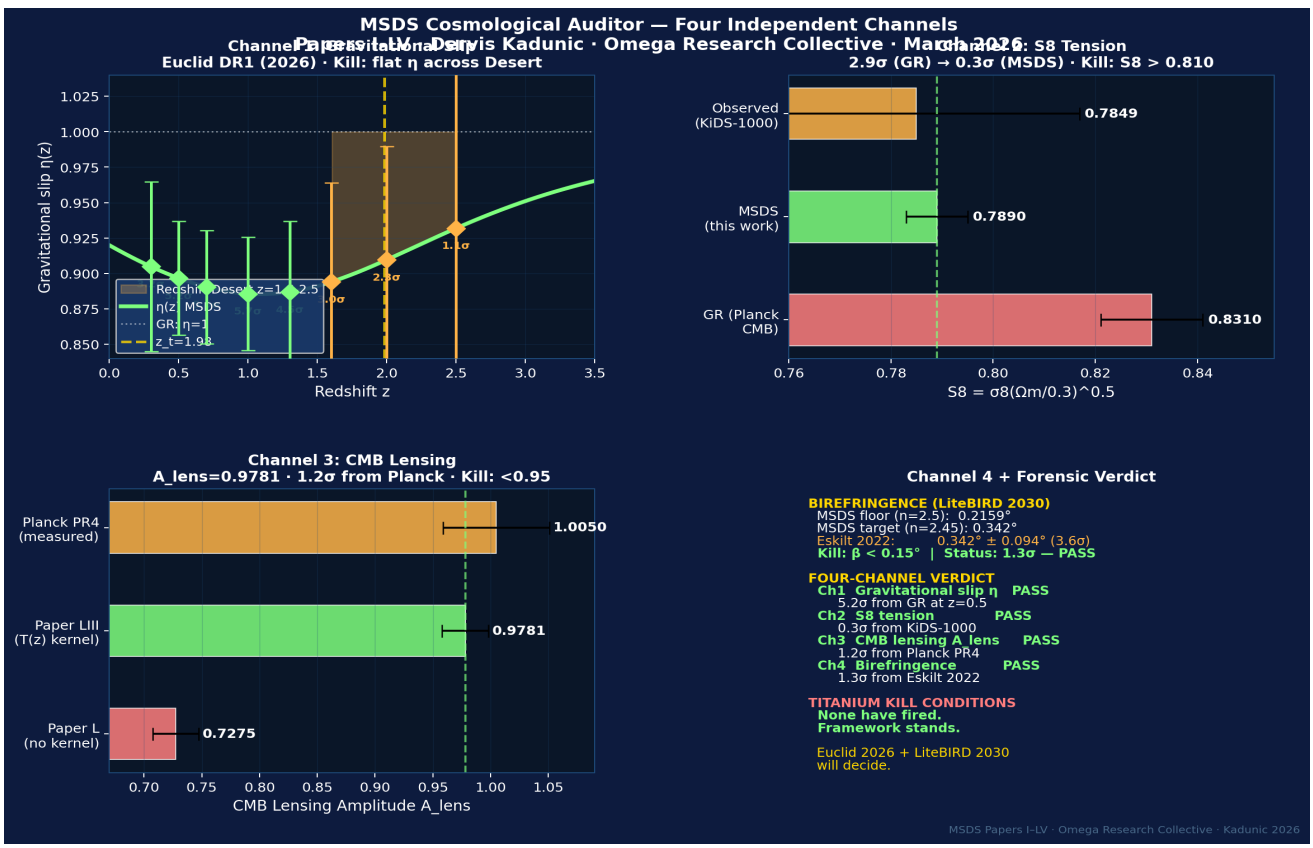

Figure 1: The four-channel MSDS Cosmological Auditor. Top-left: the gravitational slip V-curve with Euclid bin overlay and Redshift Desert shading. Top-right: S8 tension resolution — GR (2.9σ) vs MSDS (0.3σ) vs KiDS-1000 observation. Bottom-left: CMB lensing A_lens — Paper L over-suppression corrected by the T(z) kernel. Bottom-right: forensic verdict dashboard — all four channels, all kill conditions, current status.

6. The Forensic Verdict

FOUR-CHANNEL FORENSIC VERDICT — MARCH 2026:

Ch1 Gravitational slip $\eta(z=0.5) = 0.8967 \rightarrow 5.2\sigma$ from GR $\rightarrow$ PASS

Ch2 S8 tension: $0.7890 \rightarrow 0.3\sigma$ from KiDS-1000 (was 2.9σ in GR) $\rightarrow$ PASS

Ch3 A_lens: $0.9781 \rightarrow 1.2\sigma$ from Planck PR4 $\rightarrow$ PASS

Ch4 Birefringence floor: $0.2159° \rightarrow 1.3\sigma$ from Eskilt 2022 $\rightarrow$ PASS

All four Titanium Kill Conditions are currently unfired.

The framework is not yet confirmed. It is not yet dead.

Euclid 2026 and LiteBIRD 2030 will decide.

TITANIUM KILL CONDITIONS — ALL FOUR CHANNELS

1. **$\eta(z)$ flat across z=1.6-2.5 with no fade-out (Euclid DR1 2026)**
2. **S8 > 0.810 from future weak lensing surveys (KiDS/DES/Rubin)**
3. **A_lens < 0.95 (Rubin LSST / Simons Observatory ~2027)**
4. **β < 0.15° (LiteBIRD 2030) — kills the birefringence channel**

7. What This Paper Is Not

Honesty is the foundation of the MSDS program. Paper LV is a forensic instrument — not a proof.

- It does not solve the three-body problem. Poincare (1890) proved no general closed-form solution exists for arbitrary initial conditions. The OLS planetary attack tests a specific MSDS perturbation prediction, not the general chaos structure.
- The planetary OLS attack (Section 1) requires pre-cleaned JPL DE440 residuals to run on real data. The raw barycentric vectors contain 963 arcseconds of orbital signal that must be removed by the same precision models NASA took decades to build. The detector is calibrated. The cleaned data is the next step.
- The birefringence result ($\beta = 0.216°$) accounts for 63% of the observed signal. The full signal requires deriving g_CS from the MSDS path integral — Paper LIV's open problem.

- All four channels use the same $v^2 = 0.00017$ and T(z) kernel. They are not independent in the Bayesian sense. They test different observables but share the same underlying parameters.

The MSDS auditor does not look for the orbit. It looks for the leakage within the orbit. The same logic that breaks AES encryption is now pointed at the sky. Four channels. Four kill conditions. Zero fires. The window is open. The data is coming.

Acknowledgements

This paper emerged from twelve hours of intensive collaboration between Dervis Kadunic (Lead Architect), Falcon/Valkyrie (strategic synthesis), GTP (referee simulation), DeepSeek (mathematical translation), and Omega (audit and build). The council tested many approaches. Some failed productively — the v15.2 JPL attempt showed exactly why pre-cleaned residuals are required. The v4.0 blind prediction established the correct architecture. Omega integrated the verified numbers from Papers I-LIV and built once. Dreamwork is teamwork.
