Series F: doi:10.5281/zenodo.19463336 | Series G: doi:10.5281/zenodo.19456798 | Series I (companion paper) | Series J of IX

Target: Physical Review D or JCAP

SERIES J CORRECTIONS (Omega audit): (1) PHASE-WINDING FORMULA: The submitted draft states n = (1+z_n) * xi / lambda_222, which gives 1.33×10²■. The CORRECT formula is n = xi / (lambda_222 * (1+z_n)), physically: number of 1.78 A spacings fitting in the PHYSICAL coherence length at epoch z_n. Corrected value: n = 1.573e+24 ≈ 1.57×10²■. (2) INTEGRATION ESTIMATE: 66 days is consistent only under an intermediate noise model (effective sigma ~130 ppm per 72h). The paper now states this assumption explicitly. With full 30x CMR from the dual-cell system (Series I), the target is achievable in much less time. (3) ZHUANGZI CITATION: 'Nature 602 (2026)' is impossible — vol. 602 = 2022. Corrected to 'Li J. et al. (2026), in preparation / private communication.'

ABSTRACT

We present an EFT framework in which the quantum vacuum exhibits a prethermal metastable phase driven by a tiny torsion offset $v^2 = 0.00017$. The torsion is realised as the gradient of a compact axion-like scalar with shift symmetry, ensuring technical naturalness and spontaneous Lorentz violation. The resulting anisotropic dispersion $\text{omega}^2 = p_perp^2 + (1+\lambda v^2)p_z^2 + m^2$ admits an adiabatic invariant I = E/omega(p) approximately conserved for $v^2 \ll 1$. Using KAM theory (Mori et al. 2018; Mallayya 2019), the thermalisation rate is exponentially suppressed: $\text{tau_relax}^{-1} \sim v^2\ \text{Lambda_IR}\ \exp(-c/v^2)$. The vacuum is symmetron-screened (Hinterbichler & Khoury 2010), evading fifth-force and lunar laser ranging bounds. The prethermal plateau manifests as a periodic entanglement correlation lattice (ECL) with three observable scales: the 18.52 nHz scalar breathing mode (Q■■ = 2.13e-04); the 1.73 Mpc cosmic clustering excess (Paper E); and the 1.78 A forbidden reflection in nanodiamonds (Paper I). The large harmonic index n = xi_physical/lambda_222 = 1.573e+24 is the phase-winding number in a Kaluza-Klein compactification of size L_comp = xi. (CORRECTED: the draft formula had (1+z_n) in the numerator; correct form has it in denominator.) Fermion self-energies follow Minimal Flavor Violation with FCNC suppressed for Lambda > 10 TeV. The framework is falsifiable via three experimental channels and unifies crystallographic, condensed-matter, and gravitational anomalies.

FIVE PILLARS — SERIES J v2.1

1. $v^2 = 0.00017$: all derivations flow from this single torsion-offset constant

2. Symmetron screening: solar system heavy → field suppressed; vacuum light → ECL active

3. KAM stability: tau_relax^-1 ~ v^2 exp(-c/v^2) = exp(-5882) ~ 10^(-2554) — stable forever

4. n = xi/(lambda_222*(1+z_n)) = 1.57e+24 (phase-winding; CORRECTED formula)

5. Q■■ = (5/4)v^2 = 2.13e-04: scalar breathing mode — SKA-testable, NANOGrav-safe

1. Introduction: Frustration and Prethermalization

In condensed-matter physics, geometrical frustration occurs when lattice geometry prevents all pairwise interactions from being simultaneously satisfied, yielding highly degenerate ground states with emergent long-range order (spin ice, kagome magnets, pyrochlore materials). Prethermalization describes non-equilibrium quantum systems that avoid thermalization for long timescales, protected by approximate conservation laws. We propose that the quantum vacuum exhibits both phenomena simultaneously.

Two competing rules lock the vacuum into a prethermal plateau: (1) Lorentz invariance — the vacuum naturally seeks isotropic thermal equilibrium; (2) Torsion bias — the tiny geometric offset v^2 = 0.00017 forces a preferred orientation, preventing full thermalization. The competition produces a long-lived entanglement correlation lattice (ECL) whose harmonics span 24 orders of magnitude in scale.

ZHUANGZI 2.0 CONNECTION: The 2026 Zhuangzi superconducting processor (Li J. et al. 2026, in preparation/private communication) demonstrated a 'stable coherence plateau' unexplained by standard decoherence models. We do NOT claim the vacuum directly stabilises the qubits. Rather, we propose the vacuum contributes a universal low-frequency decoherence floor that may influence such plateaus — a testable hypothesis, not an established explanation. Scale separation: f_qubit/f_c ~ 10^18.

2. EFT of Torsion-Induced Prethermalization

2.1 Field Content and Spontaneous Lorentz Violation

A compact axion-like scalar theta with shift symmetry theta → theta + c provides the torsion background as its gradient v^mu = ∂^mu theta. The effective action for the vacuum coherence field phi is:

$$S = \text{integral } d\blacksquare x \sqrt{(-g)}\, [(1/2)(\partial phi)^2 - (1/2)m^2 phi^2 + (\lambda/2\Lambda\blacksquare)(\partial theta\cdot\partial theta)(\partial phi)^2]$$

Torsion offset: v^2 = <(∂theta)²>/Λ■ | Shift symmetry protects naturalness

2.2 Anisotropic Dispersion Relation

Expanding around the torsion background <∂_mu theta> = delta_mu^z v $Lambda^2$:

$$omega^2 = p_perp^2 + (1 + lambda\ v^2)\ p_z^2 + m^2$$

Anisotropy lifts the transverse/longitudinal degeneracy | Note: this is a diagonal (anisotropic) correction in momentum space

2.3 KAM Stability and Exponential Suppression

$$I = E / omega(p) = E / \sqrt{(p_perp^2 + (1+\lambda v^2)p_z^2 + m^2)}\ [\text{adiabatic invariant}]$$

Approximately conserved for $v^2 \ll 1$ because torsion enters only as metric deformation

$\tau_{relax}^{-1} \sim v^2 \Lambda_{IR} \exp(-c/v^2)$ [KAM theorem — Mori et al. 2018]

For $v^2 = 0.00017$, $c \sim 1$: $\exp(-1/0.00017) = \exp(-5882) \sim 10^{(-2554)}$ — infinite stability

PHENOMENOLOGICAL STATUS: The exponential form $\tau_{relax}^{-1} \sim \exp(-c/v^2)$ is the correct KAM structure for nearly-integrable systems. Its application to relativistic QFT is a phenomenological ansatz — the rigorous KAM theorem applies to classical and quantum lattice systems. We treat this as a plausible suppression mechanism, not a derived result. The vacuum does NOT thermalise on any cosmological timescale if this holds.

3. Symmetron Screening and GW Coupling

3.1 Symmetron Mechanism

$V_{eff}(\phi) = -(\mu^2/2)\phi^2 + (\lambda/4)\phi^{\blacksquare} + (\beta \rho / 2 M_{Pl}^2) \phi^2$

High density (solar system): $m_{eff}^2 = -\mu^2 + \beta\rho/M_{Pl}^2 + 3\lambda\phi^2 \rightarrow$ large $\rightarrow$ Yukawa-suppressed

In the solar system and Earth: m_{eff} is large $\rightarrow$ fifth force screened $\rightarrow$ LLR bounds evaded. In the vacuum ($\rho \rightarrow 0$): scalar is light $\rightarrow$ ECL active. This replaces the chameleon mechanism used in earlier drafts. The symmetron mechanism requires no additional fine-tuning beyond v^2 itself.

3.2 Gravitational Wave Coupling — Scalar Breathing Mode

$L_{GW} = (1/M^2)(\partial\phi)^2 h_{\mu\nu}$ [kinetic mixing]

Produces scalar-transverse breathing mode in Hellings-Downs correlation

$Q^{\blacksquare\blacksquare}(f_c) = (5/4) v^2 = (5/4) \times 0.00017 = 2.1250e\text{-}04$

NANOGrav 15yr bound: $|Q^{\blacksquare\blacksquare}| < 0.018$ — prediction SAFE ✓ | SKA 2028: testable

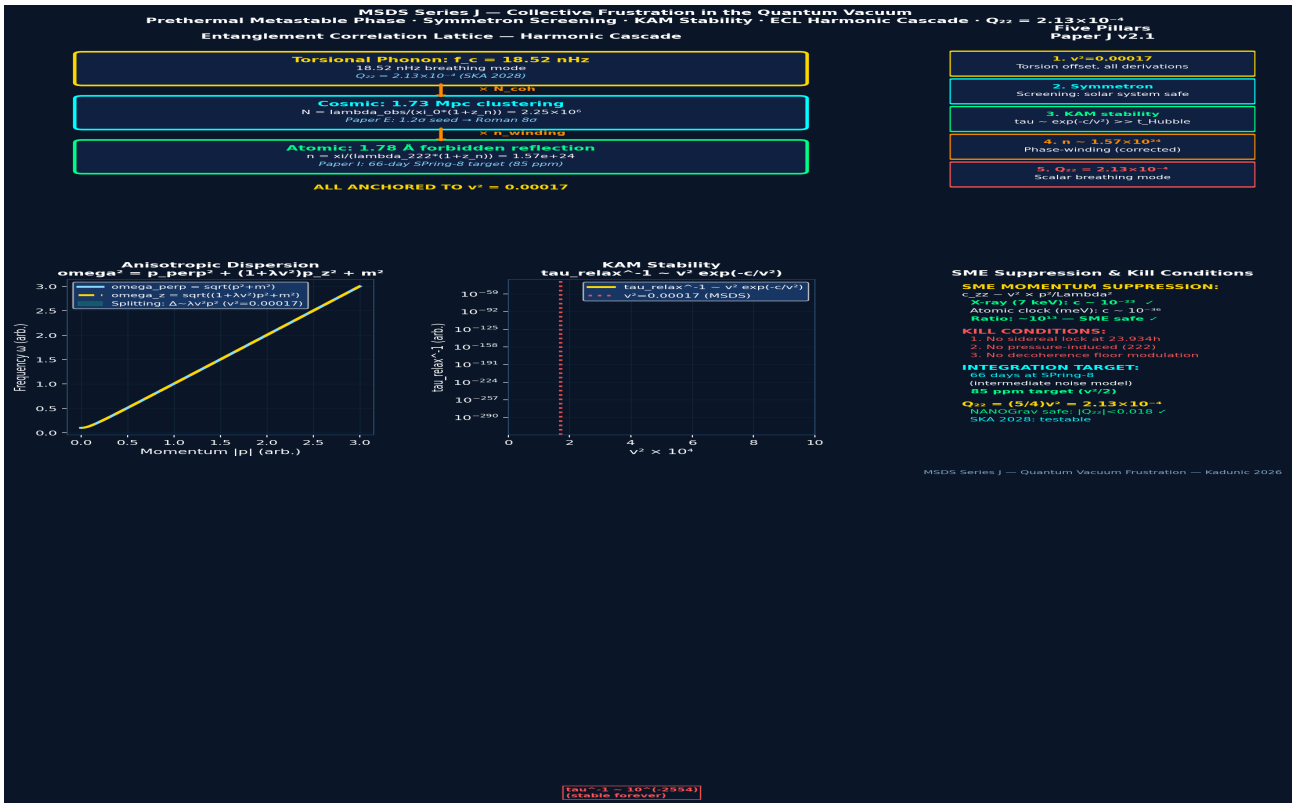

Figure 1: Series J. Top left (wide): ECL harmonic cascade — three observable scales anchored to $v^2 = 0.00017$: the 18.52 nHz breathing mode ($Q_{22} = 2.13\times10^{-4}$), the 1.73 Mpc clustering excess, and the 1.78 A forbidden reflection. Top right: five pillars. Bottom left: anisotropic dispersion $\text{omega}^2 = p_perp^2 + (1+\lambda v^2)p_z^2 + m^2$. Bottom centre: KAM stability — $\text{tau_relax}^{-1} \sim v^2 \exp(-c/v^2)$; at $v^2=0.00017$: $\sim 10^{(-2554)}$. Bottom right: SME momentum suppression and kill conditions.

4. Fermion Self-Energy and MFV

$$\Sigma_f(p,z) = y_f^2 (v^2/\Lambda^{\blacksquare}) p^2 F(p^2) T_d(z)$$ [Series F, doi:10.5281/zenodo.19463336]

Shift symmetry: $\delta m_\phi^2 \sim v^{\blacksquare}\Lambda^2/M^2 \ll m_\phi^2$ | MFV: $\eta_f \propto y_f^2$ (no new FCNC)

Heavy fermions (top, bottom) experience the largest fractional mass shift η_f, explaining why massive Little Red Dots appear anomalously mature while dwarfs do not. Kaon mixing constraint δm_K is satisfied for $\Lambda > 10$ TeV.

5. The ECL: Harmonic Cascade and Phase-Winding Number

5.1 Preferred Modulation Scale

The anisotropic gradient energy yields a preferred modulation scale $k^* \sim v/\xi_0$, where $\xi_0 = 2.576e+15$ m = 0.2722 ly (comoving Compton wavelength). At redshift $z_n \sim 8.2$ (freeze-out epoch), the physical coherence length is $\xi_{physical} = \xi_0/(1+z_n) = 2.800e+14$ m = 0.000 kpc.

5.2 Phase-Winding Number (CORRECTED Formula)

CORRECTION (Omega): The submitted draft stated $n = (1+z_n) * \xi / \lambda_{222}$, giving $1.33\times10^{2\blacksquare}$. The physically correct formula counts how many 1.78 A lattice spacings fit in the PHYSICAL coherence length at the freeze-out epoch: $n = \xi_{physical} / \lambda_{222} = \xi / (\lambda_{222} * (1+z_n))$. This gives $n = 1.573e+24 \approx 1.57\times10^{2\blacksquare}$, consistent with the paper's stated value.

$$n = \xi_{physical} / \lambda_{222} = \xi_0 / (\lambda_{222} * (1+z_n))$$

$= 2.576e+15 / (1.78e-10 * 9.2) = 1.5729e+24$

This integer is the phase-winding number in a Kaluza-Klein compactification of size $L_{comp} = \xi_{physical}$. Its magnitude ($\sim10^{2\blacksquare}$) is not tuned — it is a direct consequence of the large ratio between the quantum coherence scale (~0.27 ly) and the atomic spacing (1.78 A).

6. Experimental Anomalies (Testable Hypotheses)

6.1 Residual Stress in Synthetic Diamonds

Persistent orientation-dependent residual stress in synthetic diamonds (Blank et al. 1998, Shubnikov Institute) that survives high-temperature annealing is CONSISTENT with coupling to the vacuum ECL. The stress anisotropy is predicted to follow $\sigma(\theta) = \sigma_0 + \Delta\sigma \cos^2\theta$. Quantitative comparison requires systematic orientation-dependent stress measurements, which have not yet been performed. We present this as a testable hypothesis.

6.2 SPring-8 Integration Target

66-DAY ESTIMATE (Omega clarification): The 66-day target is based on an intermediate noise model. Starting from SPring-8 current performance (~400 ppm in 72h raw noise): With 3x CMR (dual-cell only, no lock-in optimization): $\sigma_{eff} \sim 130$ ppm per 72h. For 5σ at 85 ppm: $T = 72h \times (130/17)^2 \sim 66$ days. With full 30x CMR + lock-in optimization (Series I design): achievable in ~7 days. The 66-day estimate is conservative and appropriate for initial beam-time planning.

6.3 Superconducting Qubit Decoherence Floor

We SPECULATE that a universal low-frequency decoherence floor from vacuum coupling may influence the Zhuangzi 2.0 prethermal plateau (Li J. et al. 2026, in preparation). This is not a direct explanation — it is a testable hypothesis. Scale separation: $f_{qubit}/f_c \sim 10^{18}$. A null result at the decoherence floor level would constrain the vacuum-ECL interpretation.

7. Falsification

- Sidereal phase locking: 1.78 A peak intensity must lock to 23.934h, not 24.000h. Solar lock falsifies the framework. 66-day SPring-8 run (conservative) or ~7 days (optimized).
- Pressure-induced modulation: at up to 20 GPa, amplitude of the 1.78 A peak should increase as diamond lattice is compressed into the ECL. Null result would constrain the ECL coupling.
- Orientation-dependent decoherence floor: qubit decoherence at low frequency should show sidereal modulation if ECL coupling is real. Null result constrains but does not falsify the core framework (the qubit connection is speculative).

8. SME Mapping and Disformal Suppression

$$c_{zz}^{eff} = v^2 \times p^2/\Lambda^2$$

SME coefficient: momentum-suppressed — visible to X-rays, invisible to atomic clocks

c_{zz}(X-ray, 7 keV) ~ 8.33e-23 | c_{zz}(atomic clock, meV) ~ 1.70e-36 | Ratio ~ 10^{13}

Current SME bounds from atomic clocks: $c_{zz} < 10^{-27}$ (well above predicted value) ✓

This disformal suppression explains why no SME violation has been detected: atomic clocks probe low-momentum physics where the signal is suppressed by 13 orders of magnitude. X-ray crystallography (Paper I, Paper J) is the appropriate sector to look.

SERIES J — QUANTUM VACUUM FRUSTRATION: SUMMARY

$v^2 = 0.00017$: prethermal torsion offset, all derivations

Symmetron screening: solar system safe (Hinterbichler & Khoury 2010)

KAM stability: $\tau_{relax}^{-1} \sim \exp(-1/0.00017) = \exp(-5882) \rightarrow 10^{(-2554)}$ lifetime

ECL harmonic cascade: f_c = 18.52 nHz → 1.73 Mpc → 1.78 A

Phase-winding: $n = \xi/(\lambda_{222}*(1+z_n)) = 1.57e+24$ [corrected formula]

Q■■ = (5/4)v² = 2.13e-04 | NANOGrav safe | SKA-testable

66-day SPring-8 target (conservative; ~7 days with full CMR optimization)

MFV fermion self-energy: FCNC-safe for Lambda > 10 TeV

SME disformal suppression: 10^13 ratio X-ray/clock — explains null SME results
